# Linearizability vs. Sequential Consistency

- Both care about giving an illusion of a single copy.
  - From the outside observer, the system should (almost) behave as if there's only a single copy.
- · Linearizability cares about time.
- · Sequential consistency cares about program order.
- We need to look deeper into both concepts to understand the difference.

CSE 486/586, Spring 2013

## Linearizability

- · Linearizability
  - Should provide the behavior of a single copy
  - A read operation returns the most recent write, regardless of the clients
  - All subsequent read ops should return the same result until the next write, regardless of the clients.
- "The most recent" & "all subsequent"
  - Determined by time.
- Complication
  - In the presence of concurrency, read/write operations overlap.

CSE 486/586, Spring 2013

# **Linearizability Complications**

· Non-overlapping ops: time-based clear-cut ordering

a.write(x) \_\_\_\_\_\_a.read() \_\_\_\_\_\_a.read()

Overlapping ops: not clear-cut with time

\_\_\_\_a.write(x)
\_\_\_\_a.read()
\_\_\_a.read()
\_\_\_a.read()
\_\_\_a.write(y)

# **Linearizability Complications**

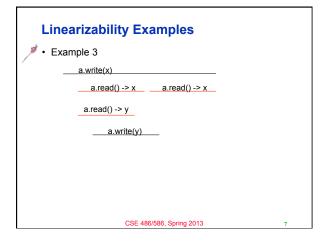

- · Non-overlapping ops: time-based clear-cut ordering
  - Global time determines "most recent write" & "subsequent reads"
- Overlapping ops: not clear-cut with time
  - The system needs to provide an ordering of ops.
  - The ordering should give an illusion that it has a single copy.
- I.e., some ordering of operations where:
  - A read returns the result of the most recent write.
  - Once the result of the write becomes visible, all subsequent reads return the same result until the next write becomes visible.

### **Sequential Consistency**

- To the outside observer, the system needs to provide a global ordering of operations where:
  - It works like a single copy.
  - The ordering of ops coming from the same client is preserved.
- · Linearizability vs. sequential consistency
  - With sequential consistency, the system has freedom as to how to interleave operations coming from different clients, as long as the ordering from each client is preserved.
  - With linearizability, the interleaving across all clients is pretty much determined already based on time.

13

# **Sequential Consistency Examples**

• Example 1

- P1: a.write(A)

- P2: a.write(B)

- P3: a.read()->B a.read()->A

- P4: a.read()->B a.read()->A

Example 2

- P1: a.write(A)

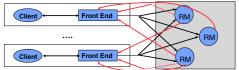

- P2: a.write(B)

- P3: a.read()->B a.read()->A

- P4: a.read()->A a.read()->B

# **Active Replication**

- Request Communication: The request contains a unique identifier and is multicast to all by a reliable totally-ordered multicast.
- Coordination: Group communication ensures that requests are delivered to each RM in the same order (but may be at different physical times!).
- Execution: Each replica executes the request. (Correct replicas return same result since they are running the same program, i.e., they are replicated protocols or replicated state machines)
- Agreement: No agreement phase is needed, because of multicast delivery semantics of requests
- Response: Each replica sends response directly to FE

15

# **Summary**

- · Linearizability
  - The ordering of operations is determined by time.
  - Primary-backup can provide linearizability.
  - Chain replication can also provide linearizability.
- · Sequential consistency
  - The ordering of operations preserves the program order of each client.
  - Active replication can provide sequential consistency.
